1 Rust in a Nutshell

1.1 Why Rust?			
1.2 Cargo			
1.3 Cargo Doc			
1.4 Crates			
1.5 Basic Data Structures			
1.5.1 Sequences			
1.5.1.1 Vec			
1.5.1.2 VecDeque			
1.5.1.3 LinkedList			
1.5.2 Maps			
1.5.2.1 HashMap			
1.5.2.2 BTreeMap			
1.5.3 Sets			
1.5.3.1 HashSet			
1.5.3.2 BTreeSet			
1.5.4 Other			
1.5.4.1 BinaryHeap			
1.6 Basic Algorithms			
1.7 Other Useful things			

4

- 1.8 Regex
- 1.9 Derive Macros

2 Macros for Rust

2.1 A macro for testing

Unlike C and C++, a testing framework is built into rust. We can create our own tests by creating a mod block and letting cargo know that we want to test it.

Let's say we create this function:

```
fn add(a: i32, b: i32) -> i32 {
   a + b
}
```

We can test it at the bottom of the file:

```
#[cfg(test)]
mod test {
   use super::*;

   #[test]
   fn add_one_and_one() {
      assert_eq!(add(1, 1), 2);
   }

   #[test]
   fn add_one_and_two() {
      assert_eq!(add(1, 2), 3);
   }
}
```

Macros let us reduce most of the boilerplate:

```
)*
}
}
```

Test can then be called like so:

```
test! {
  add_one_to_one: add(1, 1), 2,
  add_one_to_two: add(1, 2), 3,
}
```

3 Trees

3.1 Maximum Path through a Binary Tree

```
use crate::*;
use std::cmp::max;
/// Finds the maximum path sum through a binary tree.
pub fn max_path_sum(root: BSTNode) -> i32 {
  let mut max_so_far = i32::MIN;
  fn helper(node: &BSTNode, max_so_far: &mut i32) -> i32 {
    match node {
      Some(n) \Rightarrow \{
        let val = n.borrow().val;
        let l = max(0, helper(&n.borrow().left, max_so_far));
        let r = max(0, helper(&n.borrow().right, max_so_far));
        *max_so_far = max(*max_so_far, val + 1 + r);
        val + max(1, r)
      }
      None \Rightarrow 0,
    }
  }
  helper(&root, &mut max_so_far);
  max_so_far
}
test! {
    test_1: max_path_sum(btree![1,2,3]), 6,
    test_2: max_path_sum(btree![-10, 9, 20, null, null, 15, 7]), 42,
}
```

3.2 Validate Binary Search Tree

```
use crate::*;
pub fn is_valid_bst(root: BSTNode) -> bool {
    fn helper(node: &BSTNode, possible_min: i64, possible_max: i64) -> bool {
        if let Some(n) = node {
```

```
let borrowed = n.borrow();
            let left = &borrowed.left;
            let right = &borrowed.right;
            let val: i64 = borrowed.val.into();
            if val >= possible_min && val <= possible_max {</pre>
                helper(&left, possible_min, val) && helper(&right, val, possible_max)
            } else {
                false
            }
        } else {
            true
    helper(&root, i64::MIN, i64::MAX)
}
test! {
    test_1: is_valid_bst(btree![2, 1, 3]), true,
    test_2: is_valid_bst(btree![5, 1, 3]), false,
```

3.3 Same Tree

3.3.1 Problem

3.3.2 Intuition

3.3.3 Test Cases

```
test! {
    test_1: is_same_tree(btree![1,2,3], btree![1,2,3]), true,
    test_2: is_same_tree(btree![1,2,3,4], btree![1,2,3]), false,
}
```

3.3.4 Answer

```
/// Calculates if two binary search trees have the same values.
/// In this question, there are four possible cases:
/// 1. Both left and right point to a `None` node. In this case, return true.
/// 2. Either left or right points to a `None` node, but the other has a value. In

which case, return false.
```

```
/// 3. Both left and right point to a node with a value, but the values are different.

→ return false.

/// 4. Both left and right point to nodes with the same value. Return true.
/// Afterwards
pub fn is_same_tree(p: BSTNode, q: BSTNode) -> bool {
    fn same(p: &BSTNode, q: &BSTNode) -> bool {
        match (p, q) {
            (Some(left), Some(right)) => {
                let left = left.borrow();
                let right = right.borrow();
                left.val == right.val
                    && same(&left.left, &right.left)
                    && same(&left.right, &right.right)
            }-
            (None, None) => true,
            (None, _) | (_, None) => false,
        }
    same(\&p, \&q)
}
```
